

Understanding User Interface Design

Christopher Khalil
Usability Architect
Abingdon, UK

Introduction

"In successful mature technologies it's not possible to isolate the form and function. The logical design and the mechanical design of a pen or a piano bind their mechanism with their user interface so closely that it's possible to use them without thinking of them as technology, or even thinking of them at all. Invisibility is the missing goal in computing. "

Neil Gershenfeld, "When Things Start to Think"

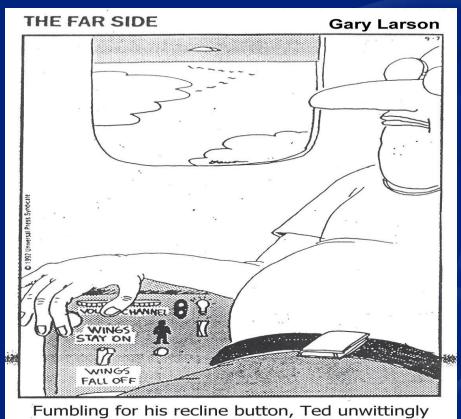

- Software industry has predilection for development of new features, bug-fixes and production of new (slightly different and "improved" versions)
- Constant "improvement" often results in an interface complexity that is constantly in a state of flux.
- Functionality creep and inconsistencies arise.
- Not enough HCI people involved
- Inattention to user needs and lack of user testing
- Interface added as an after thought, subservient to underlying technology

Often Leads To An Interface Like This

instigates a disaster.

User Interface Economics

Good user interface may result in:

Increased productivity

Reduced training costs

User satisfaction

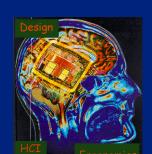

Higher quality products produced

Preventable user errors

"A computer lets you make more mistakes faster than any invention in human history - with the possible exceptions of handguns and tequila."

-Mitch Ratcliffe

What is Usability?

ISO Definition of Usability

"The effectiveness, efficiency, and satisfaction with which specified users achieve specified goals in particular environments"

A usable product allows users to do what they *expect* and *should* be able to do:

Quickly

Accurately

Enjoyably

What is HCI?

Human-Computer Interaction Definition:

"to provide an understanding of how users function, the tasks they need to perform and the way a computer system needs to be structured to facilitate the carrying out of those tasks" - Faulkner

Combines Many Disciplines:

Computer Science: technology, software tools and methodologies

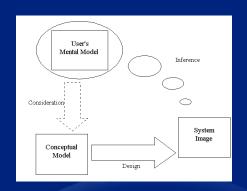

Cognitive psychology: representation and process information

Ergonomics: peoples abilities and limitations, particularly with regard to the physical working environment surrounding the computer system

Not restricted to GUI, can include haptic, audio and multimedia.

HCI encompasses usability: biggest challenges lie in augmented and ubiquitous computing

Goal Of Usability

- Interface matches users mental model make intuitive
- Present **exactly** the **information** the user requires —and no moreat exactly the **moment** it is needed
- Produce more **goal** oriented interfaces rather than **function** oriented
- Reduce amount of technology induced **complexity** at the interface
- Let the machine do the operations its better at
- Consider email..

Why is Usability Important?

"The most compelling IT solutions are ones that are simple, natural to use, and completely in tune with users' needs and experiences. Achieving this requires building a multi-disciplinary team and involving users throughout the development process" - Tony Temple, IBM Fellow and VP.

Popular assumption is software products often **compete** on the **number** of **features** they have.

Number of features only improve product if actually **used**. Proliferation of features can cause more **complexity** than **value**.

Most powerful engineering feats are the ones we don't notice.

The automatic transmission is significantly more complex than

manual transmission

Key Is Simplicity

A complex system that works is invariably found to have evolved from a simple system that worked." - John Gall

Simplicity does not mean **lack of functionality**; it means a fast initial **learning curve** and consideration for the number of concepts the user needs to understand.

Goal to produce software that is **easy to learn** but with built in path to **higher proficiency**

Consider the **affordance** of a hammer:

"Assumed to have little knowledge about systems and computers in general"

Be clear and simple

Present a small number of meaningful functions

Have lucid error messages

Give informative feedback

Come with comprehensible training materials

Include on-line tutorials and demonstrations

Include reversibility and protection

Levels of User Experience - Expert

"Power users' thoroughly familiar with commands and meanings who want to do things rapidly"

Provide powerful commands

Allow user-defined commands

Reduce key strokes

Display only brief messages

Support high speed interaction

Give less distracting feedback

Car Metaphor

"How would a car function if it were designed like a computer? Occasionally, executing a manoeuvre would cause your car to stop and fail and you would have to re-install the engine, and the airbag system would say, "Are you sure?" before going off." -Katie Hafner

How much knowledge about a car do you need to be able to drive it?

Do the best designed cars give the driver the most information about the engine, suspension, etc?

Functionality and aesthetics both important

Good design of the driver interface to the car includes designing controls that are

obvious to use

behave in the way you expect

give fast feedback

are comfortable to use

hide unnecessary information from the user

Car Interface

Great MMI interface, user has no awareness of the immense complexity of the engine or electrical system

Engineers for engine, **Designers** for MMI.

Good affordances and feedback

Lots of user testing means invisibility

User doesn't need to know anything about car mechanics

Car does work for user, consider power steering

If A Car Was A Designed by Software Engineers

- Different cars would have the clutch and accelerator pedals in different positions (consistency)
- Dashboard is now covered in lamps, lights and gauges in no order finding speed now difficult
- No **customization**, cant move chair to fit your body shape
- Add more features to the engine every year, don't consider user (no air condition or environmental controls does nothing for performance)
- User testing of UI **important**, Car manufactures test engine and road test with users, we must do the same

How To Improve Your UI: Involve The User

Teams of developers build a technology, and then almost as an after-thought add a user interface

The ensures product won't be **designed for use**; it will be designed as a vehicle for a package of **functional** technologies.

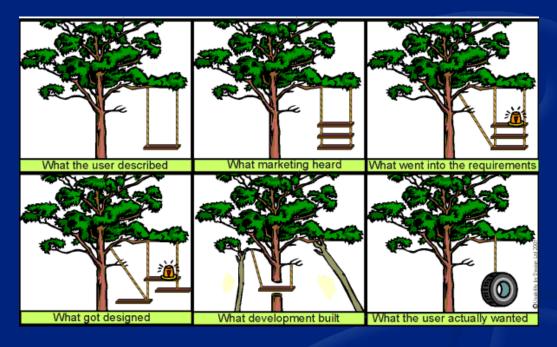

Software Engineers are not users, often complexity of the inner workings are revealed at the interface

As software designers it's easy to fall into the trap of building things that appeal to us as **creators**, instead of things that will appeal to our **customers**

There is no substitute for observing **users** actually interacting with a product. It's the only way to determine whether the projects **intended goals** match with the **reality**.

How To Improve Your UI: Involve The User

"63% of software projects exceed their budgetestim ates, with the top four reasons all relating to product usability: frequent requests for changes by users, overlooked tasks, users' lack of understanding of their own requirements, and insufficient user analysis communication and understanding."

Leaderer & Prassad, 1992

Goal is to fit the **machine** to the **person** (not vice versa!)

Cognitive issues that must be considered:

Memory (span, retrieval, storage capacity)

Visual and auditory capabilities/interpretations

Attention capacity (selective, focused, divided)

Judgment of tones, size, loudness, brightness

Interpretation of coding (traffic lights)

How To Improve Your UI: Use UI Design Guidelines

Anticipation: The user should not search for information, or evoke unnecessary tools. All the information they require and tools the need should be anticipated in design (according to goals and work flow).

Use Status Mechanisms: Keep user aware and informed. They should not have to seek out status information. I.E. Search field icon can change color and appearance.

Offer Meaningful Feedback: Provide user visual/auditory feedback to ensure 2-way communication.

Reduce Amount of Information to be memorized.

Categorize Activities by function and organize screen geography accordingly

How To Improve Your UI: Use UI Design Guidelines

Display Only Relevant Information to Context: User shouldn't have to wade through menus to obtain information.

Consider Available Geography of Display Screen: If several windows open, space should be available to show at least portion of each.

Consistency:

Very important factor, **inconsistencies** leads to **confusion**.

Also important to be **inconsistent** when things must act differently.

Most important consistency is consistency of **user expectation** (it does what the user expects, based on previous experience). Only way to ascertain user experience is user testing.

Help Messages: Very important, make them responsive to the problem and meaningful in context.

Explorable Interfaces: Place interface somewhere between dictation and total freedom. Give cues as to next step within organization of interface. Allow for both experienced and novice users.

Make Actions Reversible: Allow users to explore, implement UNDO actions. Gives users sense of safety and allows more direct use. Use of undo is far more cognitively effective than preventative measures such as "Are you REALLY sure, you want to take this action?"

Clarity: Clarity is an important issue, visual displays that are clear and concise aid user assimilation of information, and improve usability dramatically

How To Improve Your UI: Use UI Design Guidelines

Use Size/Function of Objects: The time it takes to acquire a target is a function of its size and distance to target. Make important buttons (menus) larger (big buttons are faster)

Latency Reduction: Utilize Multithreading to push latency to the background. Multi-task instead of locking user into a function. Set of simple rules for latency:

- Display hour glass for actions over 1.5 seconds
- Animate hourglass so they know system hasn't died
- Display message to show potential length over 2 seconds
- Communicate actual length through progress indicator.
- Make a BEEP or large VISUAL cue when system returns from long processes (>10 seconds).

How To Improve Your UI: Use UI Design Guidelines

Metaphors Important: Select meaningful icons.

Readability: Much of the information imparted by a HCI is **textual**, therefore the layout and form of the text has a significant impact on the ease with which the user assimilates information.

System Response Time - Length and Variability: Too long unacceptable. Too much variability breaks rhythm of interaction.

Error Information Handling: Errors presented to the user should:

Be described in easily understandable form

Contain information on what to do next, how to recover.

Indicate negative consequences of error (potentially corrupted data)

Accompanied by visual/audio cue

NEVER blame user (YOU did the wrong thing)

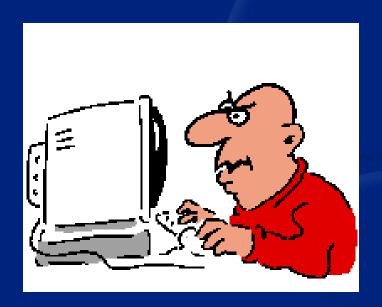

How To Improve Your UI: Add Customisation

- Make **default representation** suitable for all users (including novices)
- **Customisation** allows user to make the interface more easily reflect their preferences and thought processes
- Allows hidden complexity to be revealed when needed
- Macros/Learning by examples can eliminate the need for unnecessary **repetition**
- Allows the product to grow, as the users experience and knowledge grows

How To Improve Your UI: Don't Forget The Details!

Ease of use is not wholly about design decisions at the top level It is often the trivial points that most frustrate users

How To Improve Your UI: Don't Forget The Details!

- Theory called **Learned Helplessness**, developed Seligman
- Great deal of depression grows out of a feeling of helplessness
- Often small, but alter moods, frequently overlooked
- By paying attention to these details, user satisfaction can be increased dramatically
- Small things can pay off: Bookmarks, Auto-Completion

Aesthetics are how things are **shown** and **presented**, and the style in which things are communicated to the user

Aesthetics often come down to simple choices -- it's not the number of colors used, it's picking two or three complementary ones.

Improving aesthetics is all about details

The rounded corners and smooth edges

Making sure the pixels line up

Precision is what creates energy and movement in a design

Makes product more competitive

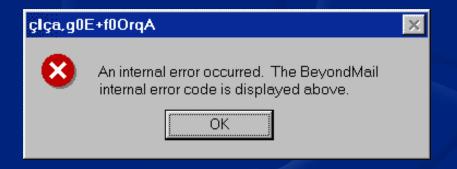

Error Messages: They should be meaningful!!

Meaningful Error Messages

Critical Error General protection fault!

History: UObject::GetFullName <- TestReach <- UObject::GetFullName <- UStruct::SerializeBin <- (Class. s_SWAT.s_ChildAmmoWindow weap[1]] <- UObject: Serialize <- (s_ChildAmmoWindow Transient.s_ChildAmmoWindow33] <- TestReach <- (s_ChildAmmoWindow Transient.s_ChildAmmoWindow33) <- UStruct::SerializeBin <- (Class UTMenu.SpeechButton NextSiblingWindow[0]) <- UObject::Serialize <-</p> (SpeechButton Transient SpeechButton 273) <- TestReach <- (SpeechButton Transient SpeechButton 273) <-UStruct::SerializeBin <- (Class UTMenu, SpeechButton NextSiblingWindow[0]) <- UObject::Serialize <-(SpeechButton Transient SpeechButton272) <- TestReach <- (SpeechButton Transient SpeechButton272) <-UStruct::SerializeBin <- (Class UTMenu.SpeechButton NextSiblingWindowf01) <- UObiect::Serialize <-[SpeechButton Transient.SpeechButton274] <- TestReach <- (SpeechButton Transient.SpeechButton274) <-UStruct::SerializeBin <- (Class UTMenu SpeechButton NextSiblingWindow(01) <- UObject::Serialize <-[SpeechButton Transient SpeechButton277] <- TestReach <- [SpeechButton Transient SpeechButton277] <-UStruct::SerializeBin <- (Class UTMenu SpeechButton NextSiblingWindow(01) <- UObject::Serialize <-[SpeechButton Transient SpeechButton276] <- TestReach <- (SpeechButton Transient SpeechButton276) <-UStruct::SerializeBin <- (Class UTMenu.SpeechButton NextSiblingWindow[0]) <- UObject::Serialize <-[SpeechButton Transient, SpeechButton278] <- TestReach <- (SpeechButton Transient, SpeechButton278) <-UStruct::SerializeBin <- (Class UTMenu, SpeechButton NextSiblingWindow(0)) <- UObject::Serialize <-[SpeechButton Transient SpeechButton275] <- TestReach <- (SpeechButton Transient SpeechButton275) <-UStruct::SerializeBin <- (Class UTMenu.SpeechButton NextSiblingWindow[0]) <- UObject::Serialize <-(SpeechButton Transient, SpeechButton271) <- TestReach <- (SpeechButton Transient, SpeechButton271) <-UStruct::SerializeBin <- (Class's SWAT's SWATWindow TopButton[0]) <- UObject::Serialize <-(s_SWATWindow Transient.s_SWATWindow1) <- TestReach <- (s_SWATWindow Transient, s. What type of key would you like to generate? If you don't know, it's recommended that you generate a Diffie-Hellman/DSS key pair. RSA is the "old-style" PGP key. Most new users of PGP will be expecting a Diffie-Hellman/DSS key. If you'd like more information on the differences between the two key types, press the Help button, below. Key Pair Type Diffie-Hellman/DSS C RSA < <u>B</u>ack Next > Cancel

Readability: Text should have necessary clarity to ensure users can disseminate information correctly.

Whenever your local SMS Administrator vends you an actual software Package, the SMS Package Command Manager will appear (usually at network logon time) displaying the available Package(s). The following screenshots display screens similar to what you will see when you receive an actual SMS Package.

To start the demonstration, elich the " $0.49\,GKHER_{0.49}^{*}GLP_{0.05}^{*}GHER_{0.6}$

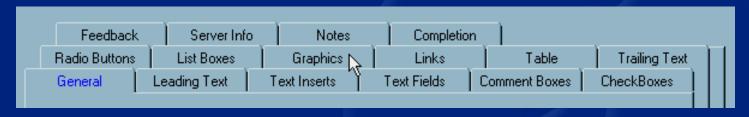

Use of Color: The color scheme should aid clarity. Too much color is distracting.

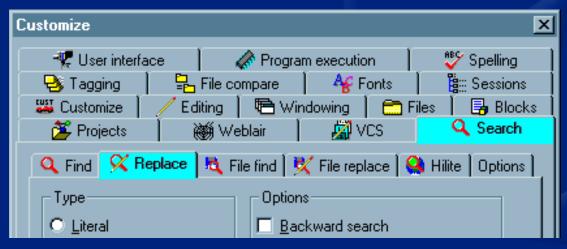

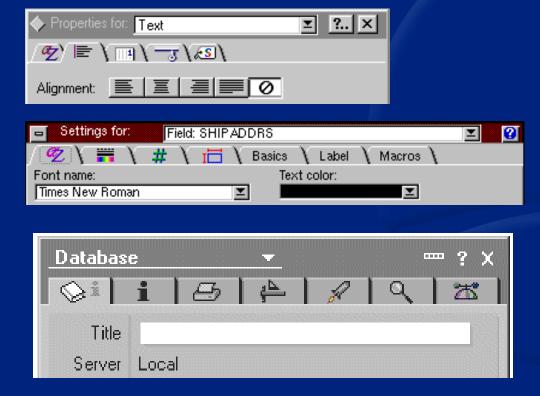

Tabbed Folders: Be judicious with use, ensure names are relevant to content.

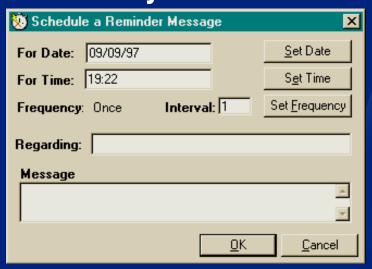

Tabbed Folders: Use text, no reason to use icons.

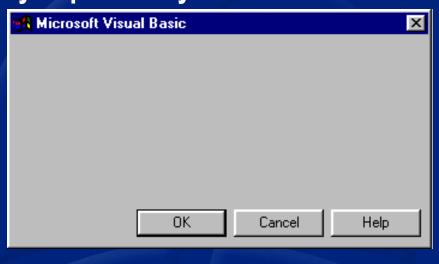

Consistency: Must work in a way expected by the user.

Augment user, do the things humans are not good at, (Can't run fast - augment by car. Can't see well - augment with glasses)

Design interface to **compensate** for our cognitively **limitation** - spatial awareness, short and long term memory.

Interconnectivity and problem solving, computer is much quicker at finding appropriate information, if information is indexed and stored correctly. (knowledge pump)

Ubiquitous computing, connect and query related computers (including devices)

Software Agents perform user's sub-goals on their behalf
Offer new interface paradigm **Indirect Management** rather than **Direct Manipulation**

Take on complex tasks on behalf of user, help manage information overload

Interface Agents, deal with humans, a least a order of complexity more difficult to deal with humans

Can negotiate with other software agents on their behalf for services.

The Future – Agents

- Increasing number of **untrained** users, have to initiate and monitor all tasks explicitly
- Agents allow **co-operative** process in which human-machine allocate tasks **appropriate** to ability
- Agents hide complexity of difficult tasks, perform on behalf of user, they can train or teach user, help user co-operate. (find other agents with similar users and connect together)
- Can aid user by making suggestions, exploring and demonstrating alternatives
- No reason why agents shouldn't converse with others to help solve problem..connect experience

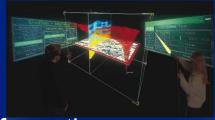

Multimedia makes inherently complex information more comprehensible.

Can transmit information in form most appropriate for type.

Use redundancy: i.e. car not just visual cues, sound and feel important (redundant because not essential to pure goal, but provide important information)

Humans prefer **parallel** sets of redundant info, i.e pool table with overhead view.

Redundancy in SIS, use of IR, haptic and audio.

As scan information, feel rock...hear water...

- Systems which change behaviour according to context.
- Novice user, simpler interface as gain experience offer more features.
- Adaptive system can improve the **cognition** for bandwidth limited systems (2 monitors) by optimising **information** shown.
- Spatial adaptation, representation adaptation (most appropriate for context)
- New representations such as **Ecological** Interfaces.
- Differentiate *skill* from *knowledge* based behaviour use to set interface level (novice->expert)

Personalization is important for future of interfaces.

Parts of interface designed with user **characteristics** in mind should support users who differ (low experience->high for example)

User should be able to adapt system to support individual strategies for **planning**, **problem solving** and **information processing**.

Allow for individual preferences with regard to structural, procedural and physical aspects.

Conclusion

Goal of user interface design is to make the experience for the user as simple, pleasurable and useful as possible.

To do this, the design must be closely aligned with the user's mental model.

The design must be usable by a novice but have the ability to be fully utilised by an expert.

To achieve this involve the user at all cycles of the software's development.

UI designer must understand *user*, *cognition* and be knowledgeable about *UI* Design Heuristics.

Details and aesthetics are as important as functionality and usability.

THANKS VERY MUCH!
